1. Base & Platform

The robot is mounted on a wheeled platform for mobility.
The rotating base supports the entire arm, so it must be strong and stable.

2. Arm Links

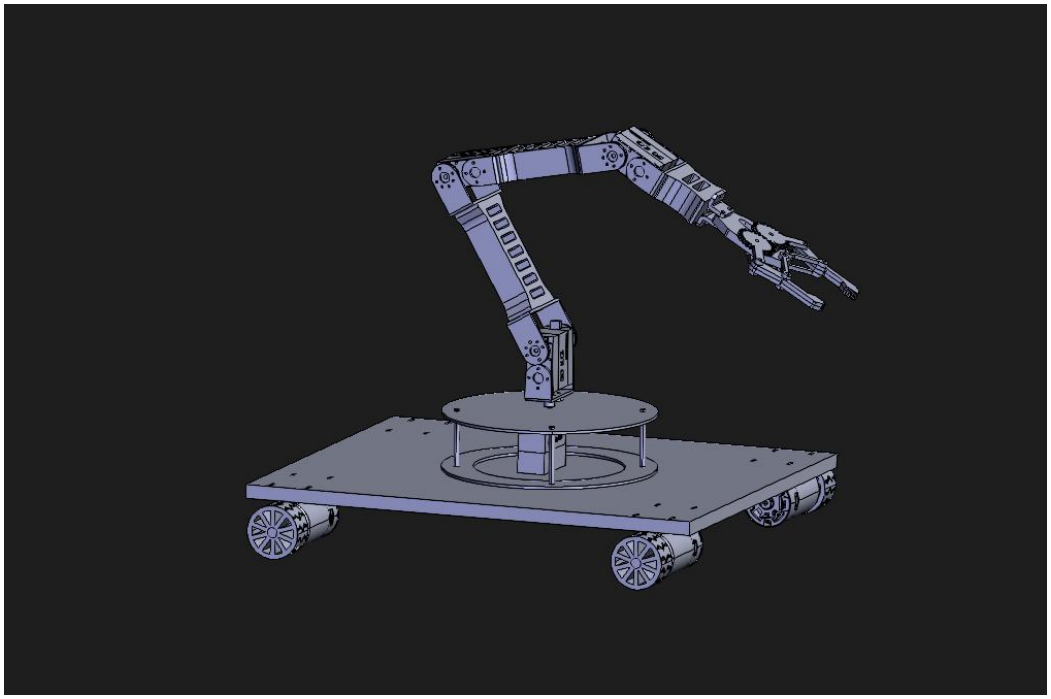
The arm uses lightweight, strong links.
Aluminium is used because it reduces motor load while maintaining stiffness and precision.

3. Joints & Motion

The joints act like a shoulder, elbow, and wrist, enabling smooth and accurate movement in multiple directions.

4. End-Effector

The gripper at the end is used to pick and hold objects, requiring both precision and strength.

5. Design Considerations


- Strong structure
- Lightweight design
- Proper load distribution
- Easy to build and modify
